## **Notation**

The key words **must**, **must not**, **required**, **should**, **should not**, **recommended**, **may** and **optional** in this document are to be interpreted as described in RFC 2119 [1].

Throughout this document, the following symbols are used:

- Indicates that the value of this parameter or field is **unknown**. The microhypervisor cannot ensure that the value does not leak information across protection domain boundaries.
- Indicates that the value of this parameter or field is **undefined**. The microhypervisor ensures that the value does not leak information across protection domain boundaries. Future versions of this specification may define a value for the parameter or field.
- \_ Indicates that the value of this parameter or field is **ignored**. Future versions of this specification may define a meaning for the parameter or field.
- Indicates that the value of this parameter or field is **unchanged**. The microhypervisor preserves the value across hypercalls.

# Part I Introduction

## 1 System Architecture

The NOVA OS Virtualization Architecture [2] (NOVA) facilitates the coexistence of multiple legacy guest operating systems and a user-mode host framework on a single platform. The core system leverages hardware virtualization technology provided by modern x86 or Arm platforms and comprises the NOVA microhypervisor and one or more Virtual-Machine Monitors (VMMs).

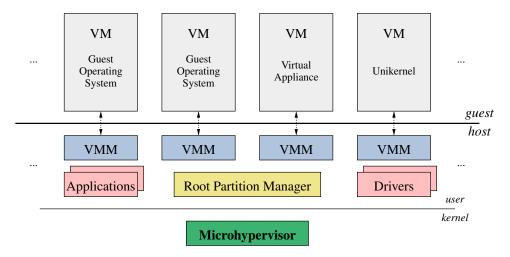

Figure 1.1: System Architecture

Figure 1.1 shows the structure of the system. The microhypervisor is the only component executing in privileged host/kernel mode. It isolates the various user-mode components, including the virtual-machine monitors, from one another by placing them in different protection domains in unprivileged host/user mode. Each legacy guest operating system runs in its own virtual-machine environment in guest mode and is therefore isolated from the other components.

Besides spatial and temporal isolation, the microhypervisor also provides mechanisms for partitioning and delegation of platform resources, such as CPU time, physical memory, I/O ports and hardware interrupts and for establishing communication channels and signaling between different protection domains.

The virtual-machine monitors handle virtualization events and implement virtual devices that enable legacy guest operating systems to function in the same manner as they would on bare-metal hardware. Providing this functionality outside the microhypervisor in the VMMs reduces the size of the trusted computing base significantly for all components that do not require virtualization support.

The architecture and interfaces of the VMM and the user-mode host framework are not described in this document.

# Part II Basic Abstractions

## 2 Kernel Objects

#### 2.1 Protection Domain

- 1. The Protection Domain (PD) is a unit of protection and spatial isolation.
- 2. Access to a Protection Domain is controlled by a PD Capability (CAP<sub>OBJpp</sub>).
- 3. Different types of spaces can be created for a PD. These spaces store Capabilities (CAPs) for kernel objects or platform resources that can be accessed by Execution Contexts in that Protection Domain.

The following table shows the types of spaces that exist  $(\checkmark)$  for each architecture and the following subsections provide more details for each space.

Architecture	<b>Object Space</b>	<b>Host Space</b>	<b>Guest Space</b>	DMA Space	PIO Space	MSR Space
Arm	✓	<b>√</b>	✓	✓		
x86	$\checkmark$	$\checkmark$	$\checkmark$	$\checkmark$	$\checkmark$	$\checkmark$

#### 2.1.1 Object Space

- 1. Only one Object Space (SPC<sub>OBJ</sub>) can be created per Protection Domain.
- 2. Access to an Object Space is controlled by an Object Space Capability (CAP<sub>OBJORI</sub>).
- 3. Each hypercall invoked by a Host Execution Context explicitly specifies an Object Capability Selector to designate the kernel object on which it operates.
- 4. The Object Capability Selector (SEL<sub>OBJ</sub>) serves as index into the EC's Object Space and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or an Object Capability (CAP<sub>OBJ</sub>) that refers to a kernel object with associated access permissions.

#### 2.1.2 Host Space

- 1. Only one Host Space (SPC<sub>HST</sub>) can be created per Protection Domain.
- 2. Access to a Host Space is controlled by a Host Space Capability (CAP<sub>OBJ<sub>HST</sub></sub>).
- 3. Each memory operation issued by a Host Execution Context implicitly uses the page number of the accessed Host-Virtual Address (HVA) as Host Capability Selector: SEL<sub>HST</sub> = HVA >> 12.
- 4. The Host Capability Selector (SEL<sub>HST</sub>) serves as index into the EC's Host Space and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or a Memory Capability (CAP<sub>MEM</sub>) that refers to a 4 KiB page frame in physical memory with associated access permissions.

## 2.1.3 Guest Space

- 1. Multiple Guest Spaces (SPC<sub>GST</sub>) can be created per Protection Domain.
- 2. Access to a Guest Space is controlled by a Guest Space Capability (CAP<sub>OBJGST</sub>).
- 3. Each memory operation issued by a Guest Execution Context implicitly uses the page number of the accessed Guest-Physical Address (GPA) as Guest Capability Selector: SEL<sub>GST</sub> = GPA >> 12.
- 4. The Guest Capability Selector (SEL<sub>GST</sub>) serves as index into the EC's Guest Space and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or a Memory Capability (CAP<sub>MEM</sub>) that refers to a 4 KiB page frame in physical memory with associated access permissions.

## 2.1.4 DMA Space

- 1. Multiple DMA Spaces (SPC<sub>DMA</sub>) can be created per Protection Domain.
- 2. Access to a DMA Space is controlled by a DMA Space Capability (CAP<sub>OBJDMA</sub>).
- 3. Each DMA operation issued by a device implicitly uses the page number of the accessed DMA-Virtual Address (DVA) as DMA Capability Selector: SEL<sub>DMA</sub> = DVA >> 12.
- 4. The DMA Capability Selector (SEL<sub>DMA</sub>) serves as index into the device's DMA Space and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or a Memory Capability (CAP<sub>MEM</sub>) that refers to a 4 KiB page frame in physical memory with associated access permissions.

#### 2.1.5 PIO Space

- 1. Multiple PIO Spaces (SPC<sub>PIO</sub>) can be created per Protection Domain.
- 2. Access to a PIO Space is controlled by a PIO Space Capability (CAP<sub>OBJ<sub>PIO</sub></sub>).
- 3. Each PIO access (IN/OUT instruction) issued by an Execution Context (EC) implicitly uses the number of the accessed I/O port as PIO Capability Selector.
- 4. The PIO Capability Selector (SEL<sub>PIO</sub>) serves as index into the EC's PIO Space and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or a PIO Capability (CAP<sub>PIO</sub>) that refers to the I/O port SEL<sub>PIO</sub> with associated access permissions.

## 2.1.6 MSR Space

- 1. Multiple MSR Spaces (SPC<sub>MSR</sub>) can be created per Protection Domain.
- 2. Access to an MSR Space is controlled by an MSR Space Capability (CAP<sub>OBJ<sub>MSR</sub></sub>).
- 3. Each MSR access (RDMSR/WRMSR instruction) issued by an Execution Context (EC) implicitly uses the number of the accessed MSR as MSR Capability Selector.
- 4. The MSR Capability Selector (SEL<sub>MSR</sub>) serves as index into the EC's MSR Space and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or an MSR Capability (CAP<sub>MSR</sub>) that refers to the MSR SEL<sub>MSR</sub> with associated access permissions.

## 2.2 Execution Context

- 1. The Execution Context (EC) is an abstraction for an activity within a PD.
- 2. Access to an Execution Context is controlled by an EC Capability (CAP<sub>OBJEC</sub>).
- 3. An EC is permanently bound to one CPU.
- 4. An EC contains architecture-dependent state, such as
  - Central Processing Unit (CPU) registers
  - Floating Point Unit (FPU) registers (optionally)

The following subsections provide more details for each type of Execution Context.

#### 2.2.1 Host Execution Context

- 1. There exist two types of Host Execution Context (EC<sub>HST</sub>):
  - Local Threads these may have PTs (but no SCs) bound to it.
  - Global Threads these may have an SC (but no PTs) bound to it.
- 2. A Host Execution Context has a UTCB that enables it to perform regular IPC.
- 3. Upon creation, a Host Execution Context is permanently bound to the following required spaces of its PD:
  - The first Object Space\*
  - The first Host Space\*
  - The first PIO Space<sup>†</sup>
- 4. A Host Execution Context cannot be reassigned to any spaces.

#### 2.2.2 Guest Execution Context

- 1. There exists one type of Guest Execution Context (EC<sub>GST</sub>):
  - Virtual CPUs these may have an SC (but no PTs) bound to it.
- 2. A Guest Execution Context does not have a UTCB.
- 3. Upon creation, a Guest Execution Context is permanently bound to the following required spaces of its PD:
  - The first Object Space\*
  - The first Host Space\*
- 4. Upon any architectural/microhypervisor event, a Guest Execution Context may be (re)assigned to the following spaces of its PD, by setting the SPACES bit in the MTD and providing selectors that refer to capabilities with ASSIGN permission for these spaces in the respective UTCB fields during ipc\_reply:
  - Any Guest Space
  - Any PIO Space<sup>†</sup>
  - Any MSR Space<sup>†</sup>

The handler of the STARTUP event must perform the initial assignment of these spaces.

<sup>\*</sup>Because only one such space can be created for a PD, it is also the only such space.

<sup>†</sup>Only on architectures, where this type of space exists.

## 2.3 Scheduling Context

- 1. The Scheduling Context (SC) is a unit of prioritization and temporal isolation.
- 2. Access to a Scheduling Context is controlled by an SC Capability (CAP<sub>OBJsc</sub>).
- 3. An SC is permanently bound to one CPU.
- 4. An SC is permanently bound to the EC for which it was created.
- 5. Donation allows another EC to consume the budget of the SC for the duration of the donation.
- 6. A scheduling context comprises the following state:
  - Reference to bound EC (2.2)
  - Class Of Service (COS)
  - Priority numerically higher priorities always preempt numerically lower priorities
  - Budget time after which the SC can be preempted by an SC with the same priority

#### 2.4 Portal

- 1. A Portal (PT) represents a dedicated entry point into the PD for which the portal was created.
- 2. Access to a Portal is controlled by a PT Capability (CAP<sub>OBJ<sub>PT</sub></sub>).
- 3. A PT is permanently bound to the EC for which it was created.
- 4. A portal comprises the following state:
  - Reference to bound EC (2.2)
  - Message Transfer Descriptor (MTD) (4.4)
  - Entry Instruction Pointer (IP)
  - Portal Identifier (PID)

## 2.5 Semaphore

- 1. A Semaphore (SM) provides a means to synchronize execution and interrupt delivery by selectively blocking and unblocking Execution Contexts (ECs).
- 2. Access to a Semaphore is controlled by a SM Capability (CAP<sub>OBJ<sub>SM</sub></sub>).

## 3 Hardware Resources

## 3.1 System Time Counter

The system time is represented by an unsigned 64-bit System Time Counter (STC) with the following properties:

- 1. The STC starts with a power-on value of 0.
- 2. Subsequent reads of the STC return a higher value that reflects the platform uptime.
- 3. While the platform is in a shallow sleep state, the STC retains its current value.
- 4. While the platform is running, the STC monotonically increments at a fixed frequency, which is conveyed in the Hypervisor Information Page (HIP).
- 5. The STC and its frequency are synchronized across all CPUs. Applications can use both values to convert between system time and wall clock time.
- 6. Applications can obtain the current STC value as follows:

**Arm:** By reading CNTVCT\_ELO via the MRS instruction [3].

**x86:** By reading IA32\_TSC via the RDTSC instruction [4, 5].

# Part III Application Programming Interface

# 4 Data Types

## 4.1 Capability

Capabilities are a communicable, unforgeable tokens of authority. They consist of a reference to a resource coupled with access permissions. Capabilities are opaque and immutable for applications – they cannot be inspected or modified directly; instead applications refer to a Capability (CAP) via a Capability Selector (SEL).

#### 4.1.1 Null Capability

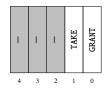

A Null Capability (CAP<sub>0</sub>) does not refer to anything and carries no permissions.

## 4.1.2 Object Capability

An Object Capability (CAPOBJ) is stored in the Object Space of a PD and refers to a kernel object.

#### 4.1.2.1 Object Space Capability

An Object Space Capability (CAP<sub>OBJOBI</sub>) refers to an Object Space and carries the following permissions:

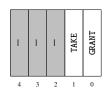

GRANT If set, ctrl\_pd can use that Object Space as destination.

TAKE If set, ctrl\_pd can use that Object Space as source.

#### 4.1.2.2 Host Space Capability

A Host Space Capability (CAP<sub>OBJ<sub>HST</sub></sub>) refers to a Host Space and carries the following permissions:

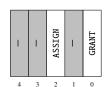

GRANT If set, ctrl\_pd can use that Host Space as destination.

TAKE If set, ctrl\_pd can use that Host Space as source.

#### 4.1.2.3 Guest Space Capability

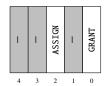

A Guest Space Capability (CAP<sub>OBJGST</sub>) refers to a Guest Space and carries the following permissions:

GRANT If set, ctrl\_pd can use that Guest Space as destination. ASSIGN If set, ipc\_reply can assign an  $EC_{GST}$  to that Guest Space.

#### 4.1.2.4 DMA Space Capability

A DMA Space Capability (CAP<sub>OBJ<sub>DMA</sub></sub>) refers to a DMA Space and carries the following permissions:

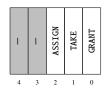

GRANT If set, ctrl\_pd can use that DMA Space as destination.

ASSIGN If set, assign\_dev can assign a device to that DMA Space.

#### 4.1.2.5 PIO Space Capability

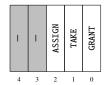

A PIO Space Capability (CAP<sub>OBJ<sub>PIO</sub></sub>) refers to a PIO Space and carries the following permissions:

 $\begin{array}{ll} \text{GRANT} & \text{If set, } \textbf{ctrl\_pd} \text{ can use that PIO Space as destination.} \\ \text{TAKE} & \text{If set, } \textbf{ctrl\_pd} \text{ can use that PIO Space as source.} \\ \text{ASSIGN} & \text{If set, } \textbf{ipc\_reply} \text{ can assign an } \textbf{EC}_{GST} \text{ to that PIO Space.} \\ \end{array}$ 

#### 4.1.2.6 MSR Space Capability

An MSR Space Capability (CAP<sub>OBJMSR</sub>) refers to an MSR Space and carries the following permissions:

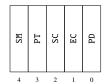

GRANT If set, ctrl\_pd can use that MSR Space as destination.

TAKE If set, ctrl\_pd can use that MSR Space as source.

ASSIGN If set, ipc\_reply can assign an EC<sub>GST</sub> to that MSR Space.

#### 4.1.2.7 Protection Domain Capability

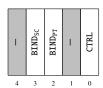

A PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) refers to a Protection Domain (PD) and carries the following permissions:

PD If set, create\_pd permitted.
EC If set, create\_ec permitted.
SC If set, create\_sc permitted.
PT If set, create\_pt permitted.
SM If set, create\_sm permitted.

#### 4.1.2.8 Execution Context Capability

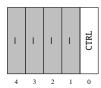

An EC Capability (CAP<sub>OBJEC</sub>) refers to an Execution Context (EC) and carries the following permissions:

 $\begin{array}{ll} \text{CTRL} & \text{If set, ctrl\_ec permitted.} \\ \text{BIND}_{PT} & \text{If set, create\_pt can bind a Portal (PT) to the EC.} \\ \text{BIND}_{SC} & \text{If set, create\_sc can bind a Scheduling Context (SC) to the EC.} \\ \end{array}$ 

#### 4.1.2.9 Scheduling Context Capability

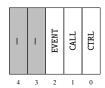

An SC Capability (CAP<sub>OBJsc</sub>) refers to a Scheduling Context (SC) and carries the following permissions:

CTRL If set, ctrl\_sc permitted.

#### 4.1.2.10 Portal Capability

A PT Capability (CAP<sub>OBJPT</sub>) refers to a Portal (PT) and carries the following permissions:

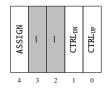

CTRL If set, ctrl\_pt permitted.

CALL If set, ipc\_call permitted.

EVENT If set, delivery of events permitted.

#### 4.1.2.11 Semaphore Capability

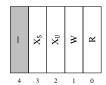

An SM Capability (CAP<sub>OBJSM</sub>) refers to a Semaphore (SM) and carries the following permissions:

 $\begin{array}{ll} {\sf CTRL_{UP}} & {\sf If set, ctrl\_sm \, (Up) \, permitted.} \\ {\sf CTRL_{DN}} & {\sf If set, ctrl\_sm \, (Down) \, permitted.} \\ {\sf ASSIGN} \ ^{\dagger} & {\sf If set, assign\_int \, permitted.} \end{array}$ 

## 4.1.3 Memory Capability

A Memory Capability (CAP<sub>MEM</sub>) is stored in a Host Space, Guest Space or DMA Space of a PD, refers to a 4 KiB page frame, and carries the following permissions:

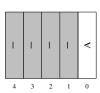

R If set, the page frame is readable. W If set, the page frame is writable.

 $X_U$  <sup>‡</sup> If set, the page frame is executable (in user mode).

 $X_S$  <sup>‡</sup> If set, the page frame is executable (in supervisor mode).

## 4.1.4 PIO Capability

A PIO Capability (CAP<sub>PIO</sub>) is stored in a PIO Space of a PD, refers to an I/O port, and carries the following permissions:

If set, the I/O port is accessible (via IN/OUT).

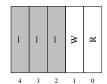

Α

<sup>&</sup>lt;sup>†</sup>This permission bit is only defined for interrupt semaphores.

<sup>&</sup>lt;sup>‡</sup>If the hardware supports only combined execute permissions (X) for both modes, then  $X = X_U \vee X_S$ .

#### 4.1.5 MSR Capability

An MSR Capability (CAP<sub>MSR</sub>) is stored in an MSR Space of a PD, refers to a Model-Specific Register (MSR), and carries the following permissions:

R If set, the MSR is readable (via RDMSR). W If set, the MSR is writable (via WRMSR).

## 4.2 Capability Selector

A Capability Selector (SEL) is an application-visible unsigned number that serves as an index into an Execution Context's space to select a Capability (CAP). The following subsections provide more details.

#### 4.2.1 Object Space Selector

An Object Capability Selector (SEL<sub>OBJ</sub>) indexes into the Object Space of an Execution Context (EC) and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or an Object Capability (CAP<sub>OBJ</sub>).

## 4.2.2 Host Space Selector

A Host Capability Selector (SEL<sub>HST</sub>) indexes into the Host Space of an Execution Context (EC) and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or a Memory Capability (CAP<sub>MEM</sub>).

## 4.2.3 Guest Space Selector

A Guest Capability Selector (SEL<sub>GST</sub>) indexes into the Guest Space of an Execution Context (EC) and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or a Memory Capability (CAP<sub>MEM</sub>).

#### 4.2.4 DMA Space Selector

A DMA Capability Selector (SEL $_{DMA}$ ) indexes into the DMA Space of an Execution Context (EC) and selects a slot that contains either a Null Capability (CAP $_0$ ) or a Memory Capability (CAP $_{MEM}$ ).

#### 4.2.5 PIO Space Selector

A PIO Capability Selector (SEL<sub>PIO</sub>) indexes into the PIO Space of an Execution Context (EC) and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or a PIO Capability (CAP<sub>PIO</sub>).

#### 4.2.6 MSR Space Selector

An MSR Capability Selector (SEL<sub>MSR</sub>) indexes into the MSR Space of an Execution Context (EC) and selects a slot that contains either a Null Capability (CAP<sub>0</sub>) or an MSR Capability (CAP<sub>MSR</sub>).

## 4.3 User Thread Control Block

A User Thread Control Block (UTCB) has a size of one memory page (4 KiB) and is mapped in the Host Space of its associated Host Execution Context. Because a UTCB is owned by the microhypervisor, it cannot be delegated using ctrl\_pd.

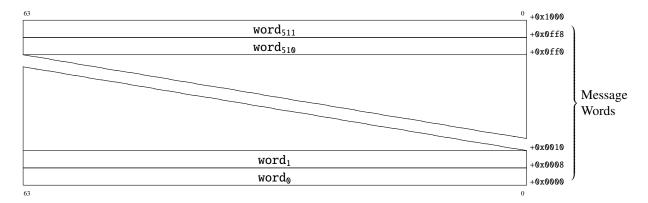

To ensure proper visibility of loads and stores with relaxed memory ordering, application programs are expected to access a UTCB only from the Host Execution Context to which that UTCB is bound.

#### 4.3.1 Regular Layout

During regular IPC (see 4.4.1), the UTCB is used for data transfer.

The data transfer from one UTCB to another UTCB is defined as follows:

- The data transfer is performed by the CPU on which the caller EC and callee EC execute.
- The data transfer uses the regular layout with 512 message words (see below).
- The data is copied from low words to high words, beginning with word<sub>0</sub>.
- The granularity of the loads and stores used for copying is **undefined**.
- Loads from and stores to the UTCB are non-atomic and use relaxed memory ordering.

#### 4.3.2 Architectural Layout

During architectural IPC (see 4.4.2), the UTCB is used for state transfer.

The state transfer between the architectural registers and a UTCB is defined as follows:

- The state transfer is performed by the CPU on which the affected EC and callee EC execute.
- The state transfer uses the architectural layout (Arm, x86).
- The state is copied between architectural registers and the UTCB in an **undefined** order.
- The granularity of the loads and stores used for copying is **undefined**.
- Loads from and stores to the UTCB are non-atomic and use relaxed memory ordering.

## 4.4 Message Transfer Descriptor

#### 4.4.1 Regular IPC

For regular Inter-Process Communication (IPC), the Message Transfer Descriptor (MTD) is provided by the sender, passed to the receiver, and uses the following layout:

The MTD controls the data transfer (see 4.3.1) as shown in Figure 4.1:

- During ipc\_call, it specifies the number of message words to transfer from the UTCB of the caller EC (sender) to the UTCB of the callee EC (receiver).
- During ipc\_reply, it specifies the number of message words to transfer from the UTCB of the callee EC (sender) to the UTCB of the caller EC (receiver).

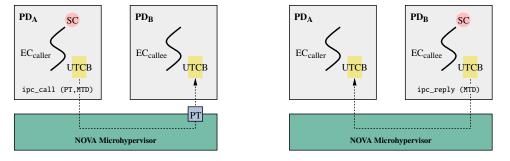

Figure 4.1: Regular IPC

#### 4.4.2 Architectural IPC

For exceptions and intercepts, the Message Transfer Descriptor (MTD) is provided by the architectural event-specific portal (Arm, x86) or sender, passed to the receiver, and uses an architectural bitfield layout (Arm, x86):

- If a bit is 0, then the microhypervisor does **not** transmit the architectural state associated with that bit.
- If a bit is 1, then the microhypervisor transmits the architectural state associated with that bit.

The MTD controls the state transfer (see 4.3.2) as shown in Figure 4.2:

- During an exception/intercept, it specifies the subset of registers to transfer from the architectural state of the affected EC (sender) to the UTCB of the callee EC (receiver).
- During ipc\_reply, it specifies the subset of registers to transfer from the UTCB of the callee EC (sender) to the architectural state of the affected EC (receiver).

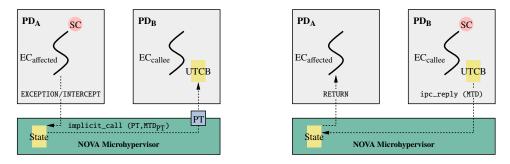

Figure 4.2: Architectural IPC

## 4.5 Scheduling Context Descriptor

The Scheduling Context Descriptor (SCD) describes the configuration of a Scheduling Context (SC).

The fields are defined as follows:

#### **Budget**

Specifies the scheduling budget in milliseconds – must be > 0.

#### Prio

Specifies the scheduling priority – must be > 0.

#### cos

Specifies the Class Of Service – valid values depend on architectural COS support (Arm, x86):

- If COS is not supported, then this field must be 0.
- If COS is supported, then this field must be  $< COS_{NUM}$ .

# 5 Hypercalls

## 5.1 Definitions

## 5.1.1 Hypercall Numbers

Each hypercall is identified by a unique number. The following hypercalls are currently defined:

Number	Hypercall	Section
0x0	ipc_call	5.2.1
0x1	<pre>ipc_reply</pre>	5.2.2
0x2	create_pd	5.3.1
0x3	create_ec	5.3.2
0x4	create_sc	5.3.3
0x5	create_pt	5.3.4
0x6	create_sm	5.3.5
0x7	ctrl_pd	5.4.1
8x0	ctrl_ec	5.4.2
0x9	ctrl_sc	5.4.3
0xa	ctrl_pt	5.4.4
0xb	ctrl_sm	5.4.5
0xc	ctrl_hw	5.5.1
0xd	assign_int	5.5.2
0xe	assign_dev	5.5.3
0xf	reserved for future use	

## 5.1.2 Status Codes

Hypercalls return a status code to indicate success or failure. The following status codes are currently defined:

Number	Status Code	Description
0x0	SUCCESS	Operation Successful
0x1	TIMEOUT	Operation Timeout
0x2	ABORTED	Operation Abort
0x3	OVRFLOW	Operation Overflow
0x4	BAD_HYP	Invalid Hypercall
0x5	BAD_CAP	Invalid Capability
0x6	BAD_PAR	Invalid Parameter
0x7	BAD_FTR	Invalid Feature
0x8	BAD_CPU	Invalid CPU Number
0x9	BAD_DEV	Invalid Device ID
0xa	MEM_OBJ	Insufficient Memory (Object Creation)
0xb	MEM_CAP	Insufficient Memory (Capability Creation)
≥0xc	reserved for future use	

## 5.2 Communication

#### 5.2.1 IPC Call

#### Parameters:

#### Flags:

#### **Description:**

Sends a message from EC<sub>CURRENT</sub> (caller) to the EC (callee) to which the specified Portal (PT) is bound. Prior to the hypercall:

• SPC<sub>OBJ<sub>CURRENT</sub></sub>[pt] must refer to a PT Capability (CAP<sub>OBJ<sub>PT</sub></sub>) with permission CALL.

If the hypercall completed successfully:

- If **T=0** (**No Timeout**): If the callee EC was still busy handling a prior ipc\_call, then the caller EC has helped run that prior ipc\_call to completion, i.e. until the callee EC became available again.
- The microhypervisor has transferred a message from the UTCB of the caller EC to the UTCB of the callee EC. The content of that message is defined by the MTD mtd, which has been passed from the caller EC to the callee EC.
- The hypercall returns once the callee EC has invoked an ipc\_reply. Upon return, the UTCB of the caller EC and the mtd parameter have been updated by the reply message.
- The Current Scheduling Context (SC<sub>CURRENT</sub>) has been donated to the callee EC upon ipc\_call and returned back upon ipc\_reply, thereby accounting the entire handling of the request to SC<sub>CURRENT</sub>.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### BAD\_CAP

 SPC<sub>OBJ<sub>CURRENT</sub></sub>[pt] did not refer to a PT Capability (CAP<sub>OBJ<sub>PT</sub></sub>) or that capability had insufficient permissions.

#### BAD\_CPU

• Caller EC and callee EC are on different CPUs.

#### **TIMEOUT**

• If **T=1** (**Timeout**): The callee **EC** is still busy handling a prior **ipc\_call**.

#### **ABORTED**

• The callee EC is dead and the operation aborted.

#### 5.2.2 IPC Reply

#### Parameters:

#### Flags:

#### **Description:**

Sends a reply message from  $EC_{CURRENT}$  (callee) back to the caller EC (if one exists) and subsequently waits for the next incoming message.

If the hypercall completed successfully:

- If a caller EC exists:
  - The microhypervisor has transferred a reply message from the UTCB of the callee EC back to the UTCB of the caller EC.
  - The content of that reply message is defined by the MTD mtd, which has been passed from the callee EC back to the caller EC.
  - The Current Scheduling Context (SC<sub>CURRENT</sub>) that had been donated to the callee EC upon ipc\_call has been returned back to the caller EC.
- EC<sub>CURRENT</sub> blocks until the next incoming message arrives on any Portal (PT) bound to it.

#### Status:

This hypercall does not return directly.

Instead, when the next message arrives via a subsequent ipc\_call to any Portal (PT) bound to the callee EC:

- The microhypervisor passes the Portal Identifier (PID) of the called PT to the callee EC.
- The UTCB of the callee EC and the mtd parameter have been updated by the incoming message.
- Execution of the callee EC continues at the Instruction Pointer (IP) configured in the called PT.

## 5.3 Object Creation

#### 5.3.1 Create Protection Domain

#### Parameters:

#### Flags:

#### **Description:**

Creates a new Protection Domain (PD) or an empty new space for a Protection Domain.

Prior to the hypercall:

- $SPC_{OBJ_{CURRENT}}[sel]$  must refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] must refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) with permission PD.

If the hypercall completed successfully:

- If **OP=0** (**Protection Domain**):
  - A new Protection Domain (PD) has been created.
  - SPC<sub>OBJ<sub>CURRENT</sub></sub>[se1] refers to a CAP<sub>OBJ<sub>PD</sub></sub> for the created Protection Domain with the permissions inherited from SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd].
- If **OP=1** (**Object Space**):
  - A new Object Space (SPC<sub>OBJ</sub>) has been created for the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
  - SPC<sub>OBJCURRENT</sub>[sel] refers to a CAP<sub>OBJOBJ</sub> for the created Object Space with all defined permissions.
- If OP=2 (Host Space):
  - A new Host Space (SPC<sub>HST</sub>) has been created for the PD referred to by SPC<sub>OBJCURRENT</sub> [pd].
  - SPC<sub>OBJ<sub>CURRENT</sub></sub>[sel] refers to a CAP<sub>OBJ<sub>HST</sub></sub> for the created Host Space with all defined permissions.
- If **OP=3** (**Guest Space**):
  - A new Guest Space (SPC<sub>GST</sub>) has been created for the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
  - SPC<sub>OBJCURRENT</sub>[se1] refers to a CAP<sub>OBJGST</sub> for the created Guest Space with all defined permissions.
- If **OP=4** (**DMA Space**):
  - A new DMA Space (SPC<sub>DMA</sub>) has been created for the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
  - SPC<sub>OBJCURRENT</sub>[sel] refers to a CAP<sub>OBJDMA</sub> for the created DMA Space with all defined permissions.
- If **OP=5** (**PIO Space**):
  - A new PIO Space (SPC<sub>PIO</sub>) has been created for the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
  - SPC<sub>OBJCURRENT</sub>[sel] refers to a CAP<sub>OBJPIO</sub> for the created PIO Space with all defined permissions.
- If OP=6 (MSR Space):
  - A new MSR Space (SPC<sub>MSR</sub>) has been created for the PD referred to by SPC<sub>OBJCHREENT</sub> [pd].
  - SPC<sub>OBJCURRENT</sub>[sel] refers to a CAP<sub>OBJMSR</sub> for the created MSR Space with all defined permissions.
- The resources for the created object were accounted to the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].

#### Status:

#### **SUCCESS**

The hypercall completed successfully.

#### **ABORTED**

- If **OP=1**: Attempted creation of more than one Object Space in the PD.
- If **OP=2**: Attempted creation of more than one Host Space in the PD.
- If **OP=5**: Attempted creation of a **PIO** Space without existing Host Space in the PD.

#### BAD\_CAP

- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sel] did not refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] did not refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) or that capability had insufficient permissions.

## BAD\_PAR

• The requested operation (OP) is invalid.

#### **BAD FTR**

• The requested space type is not supported by the hardware architecture.

#### **MEM OBJ**

• The Protection Domain referred to by SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] had insufficient memory resources for object creation.

#### MEM\_CAP

• The Protection Domain to which SPC<sub>OBJ<sub>CURRENT</sub></sub> belongs had insufficient memory resources for capability creation.

#### **5.3.2 Create Execution Context**

#### Parameters:

#### Flags:

#### **Description:**

Creates a new Execution Context (EC).

Prior to the hypercall:

- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sel] must refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] must refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) with permission EC.
- If G=0: All spaces required for a Host Execution Context must have been created for the owner PD.
- If G=1: All spaces required for a Guest Execution Context must have been created for the owner PD.

If the hypercall completed successfully:

- If G=0 (Host Execution Context):
  - A new Host Execution Context (EC<sub>HST</sub>) has been created.
  - The Host Execution Context has its UTCB mapped at virtual page number utcb and its initial Stack Pointer (SP) set to sp.
  - If T=0 (Local Thread): Portals (PTs) may subsequently be bound to that EC and the EC will run
    whenever any of those bound portals is called.
  - If T=1 (Global Thread): The EC will generate a STARTUP event the first time a Scheduling Context (SC) is bound to it.
- If G=1 (Guest Execution Context):
  - A new Guest Execution Context (EC<sub>GST</sub>) has been created.
  - The parameters utcb and sp were ignored.
  - The EC will generate a STARTUP event the first time a Scheduling Context (SC) is bound to it.
  - If **T=0** (Virtual CPU): The virtual CPU uses no time adjustment.
  - If T=1 (Virtual CPU): The virtual CPU uses time offsetting.
- The created EC will be able to use FPU instructions only if F=1 (FPU). Otherwise any FPU access by that EC will generate an architecture-specific exception.
- The created EC has its Event Selector Base (SEL<sub>EVT</sub>) set to evt, is permanently bound to the CPU cpu
  and to the required spaces of the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
- The resources for the created EC were accounted to the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sel] refers to a CAP<sub>OBJ<sub>EC</sub></sub> for the created EC with all defined permissions.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### **ABORTED**

• Required spaces are missing in the PD referred to by SPC<sub>OBJCURRENT</sub> [pd].

## BAD\_CAP

- $SPC_{OBJ_{CURRENT}}[sel]$  did not refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJCURRENT</sub>[pd] did not refer to a PD Capability (CAP<sub>OBJPD</sub>) or that capability had insufficient permissions.

## BAD\_CPU

• The CPU number is invalid.

#### BAD\_FTR

• Virtual CPUs are not supported by the hardware architecture.

#### BAD\_PAR

• The UTCB address is outside the user-accessible memory range.

#### **MEM OBJ**

• The Protection Domain referred to by SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] had insufficient memory resources for object creation.

#### MEM\_CAP

• The Protection Domain to which SPC<sub>OBJ<sub>CURRENT</sub></sub> belongs had insufficient memory resources for capability creation.

#### 5.3.3 Create Scheduling Context

#### Parameters:

#### Flags:

#### **Description:**

Creates a new Scheduling Context (SC).

Prior to the hypercall:

- SPC<sub>OBJCURRENT</sub>[sel] must refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] must refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) with permission SC.
- $SPC_{OBJ_{CURRENT}}[ec]$  must refer to an EC Capability ( $CAP_{OBJ_{EC}}$ ) with permission  $BIND_{SC}$ .

If the hypercall completed successfully:

- A new Scheduling Context (SC) has been created.
- The created SC is bound to the EC referred to by SPC<sub>OBJ<sub>CURRENT</sub></sub>[ec] on the CPU of that EC, with its scheduling parameters set according to scd.
- The resources for the created SC were accounted to the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sel] refers to a CAP<sub>OBJ<sub>SC</sub></sub> for the created SC with all defined permissions.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### BAD\_CAP

- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] did not refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) or that capability had insufficient permissions.
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[ec] did not refer to an EC Capability (CAP<sub>OBJ<sub>EC</sub></sub>) or that capability had insufficient permissions.
- Binding the SC to the EC failed, e.g. because the EC is a local thread.

#### **BAD PAR**

• At least one SCD field in scd was invalid.

#### MEM\_OBJ

• The Protection Domain referred to by SPC<sub>OBJCURRENT</sub>[pd] had insufficient memory resources for object creation.

#### **MEM CAP**

• The Protection Domain to which SPC<sub>OBJCURRENT</sub> belongs had insufficient memory resources for capability creation.

#### 5.3.4 Create Portal

#### Parameters:

#### Flags:

#### **Description:**

Creates a new Portal (PT).

Prior to the hypercall:

- SPC<sub>OBJCURRENT</sub> [sel] must refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] must refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) with permission PT.
- $\bullet \ \ SPC_{OBJ_{CURRENT}}[ec] \ must \ refer \ to \ an \ EC \ Capability \ (CAP_{OBJ_{EC}}) \ with \ permission \ BIND_{PT}.$

If the hypercall completed successfully:

- A new Portal (PT) has been created.
- The created PT is bound to the EC referred to by SPC<sub>OBJ<sub>CURRENT</sub></sub>[ec] on the CPU of that EC, with its Portal Instruction Pointer (IP) set to ip, its initial MTD set to 0 and its initial PID set to 0.
- The resources for the created PT were accounted to the PD referred to by SPC<sub>OBJCURRENT</sub>[pd].
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sel] refers to a CAP<sub>OBJ<sub>PT</sub></sub> for the created PT with all defined permissions.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### BAD\_CAP

- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sel] did not refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] did not refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) or that capability had insufficient permissions.
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[ec] did not refer to an EC Capability (CAP<sub>OBJ<sub>EC</sub></sub>) or that capability had insufficient permissions.
- Binding the PT to the EC failed, e.g. because the EC is not a local thread.

#### MEM\_OBJ

 The Protection Domain referred to by SPC<sub>OBJCURRENT</sub>[pd] had insufficient memory resources for object creation.

#### **MEM CAP**

• The Protection Domain to which SPC<sub>OBJ<sub>CURRENT</sub></sub> belongs had insufficient memory resources for capability creation.

#### 5.3.5 Create Semaphore

#### Parameters:

#### Flags:

#### **Description:**

Creates a new Semaphore (SM).

Prior to the hypercall:

- SPC<sub>OBJCURRENT</sub>[sel] must refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] must refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) with permission SM.

If the hypercall completed successfully:

- A new Semaphore (SM) has been created.
- The created SM has its initial counter value set to cnt.
- The resources for the created SM were accounted to the PD referred to by  $SPC_{OBJ_{CURRENT}}[pd]$ .
- $SPC_{OBJ_{CURRENT}}[sel]$  refers to a  $CAP_{OBJ_{SM}}$  for the created SM with all defined permissions.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### BAD\_CAP

- $SPC_{OBJ_{CURRENT}}[sel]$  did not refer to a Null Capability (CAP<sub>0</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub>[pd] did not refer to a PD Capability (CAP<sub>OBJ<sub>PD</sub></sub>) or that capability had insufficient permissions.

#### **MEM OBJ**

• The Protection Domain referred to by SPC<sub>OBJCURRENT</sub>[pd] had insufficient memory resources for object creation.

#### **MEM CAP**

• The Protection Domain to which SPC<sub>OBJ<sub>CURRENT</sub></sub> belongs had insufficient memory resources for capability creation.

## 5.4 Object Control

#### 5.4.1 Control Protection Domain

#### Parameters:

```
status = ctrl_pd (SELOBJ src,
                                             // SRC Space
                    SELOBJ dst,
                                             // DST Space
                    SEL
                           ssb,
                                             // SRC Selector Base
                    SEL
                           dsb,
                                             // DST Selector Base
                    UINT
                           ord,
                                             // Order
                    UINT
                                             // Permission Mask
                           pmm,
                   ATTR<sub>CA</sub> ca,
                                             // Cacheability Attribute
                    ATTR<sub>SH</sub> sh);
                                             // Shareability Attribute
```

#### Flags:

#### **Description:**

Takes capabilities from the source space and grants them to the destination space and thereby optionally reduces the permissions of the destination capabilities.

Prior to the hypercall:

- SPC<sub>OBJCURRENT</sub>[src] must refer to a CAP<sub>OBJ</sub> for the source space with permission TAKE.
- SPC<sub>OBJ<sub>CURRENT</sub></sub> [dst] must refer to a CAP<sub>OBJ</sub> for the destination space with permission GRANT.
- Capability Selectors ssb and dsb must be order-aligned: ssb≡0 (mod 2<sup>ord</sup>) and dsb≡0 (mod 2<sup>ord</sup>).
- Capability Selectors ssb and dsb must be equal if src refers to a PIO Space or an MSR Space.

If the hypercall completed successfully:

- If both src and dst refer to Object Spaces:
  - All CAP<sub>0</sub> and CAP<sub>OBJ</sub> from SEL<sub>OBJ</sub> range src[ssb...ssb+2<sup>ord</sup>-1] were delegated to SEL<sub>OBJ</sub> range dst[dsb...dsb+2<sup>ord</sup>-1].
  - Any pre-existing CAP<sub>OBJ</sub> in the SEL<sub>OBJ</sub> range dst[dsb...dsb+2<sup>ord</sup>-1] were revoked.
  - The parameters ca and sh were ignored.
- If src refers to a Host Space and dst refers to a Host Space or Guest Space or DMA Space:
  - All CAP<sub>0</sub> and CAP<sub>MEM</sub> from SEL<sub>HST</sub> range src[ssb...ssb+2<sup>ord</sup>-1] were delegated to SEL range dst[dsb...dsb+2<sup>ord</sup>-1].
  - Any pre-existing CAP<sub>MEM</sub> in the SEL range dst[dsb...dsb+2<sup>ord</sup>-1] were revoked.
  - If src refers to the NOVA Host Space, then the source SEL<sub>HST</sub> are physical page numbers and
    the cacheability and shareability attribute of each destination CAP<sub>MEM</sub> were set to ca and sh
    respectively.

Otherwise, the source  $SEL_{HST}$  are **virtual** page numbers and the cacheability and shareability attribute of each destination  $CAP_{MEM}$  were *inherited* from the respective source  $CAP_{MEM}$ , i.e. the parameters ca and sh were ignored.

- If both src and dst refer to PIO Spaces:
  - All CAP<sub>0</sub> and CAP<sub>PIO</sub> from SEL<sub>PIO</sub> range src[ssb...ssb+2<sup>ord</sup>-1] were delegated to SEL<sub>PIO</sub> range dst[dsb...dsb+2<sup>ord</sup>-1].
  - Any pre-existing CAP<sub>PIO</sub> in the SEL<sub>PIO</sub> range dst[dsb...dsb+2<sup>ord</sup>-1] were revoked.
  - The parameters ca and sh were ignored.

- If both src and dst refer to MSR Spaces:
  - All CAP<sub>0</sub> and CAP<sub>MSR</sub> from SEL<sub>MSR</sub> range src[ssb...ssb+2<sup>ord</sup>-1] were delegated to SEL<sub>MSR</sub> range dst[dsb...dsb+2<sup>ord</sup>-1].
  - Any pre-existing CAP<sub>MSR</sub> in the SEL<sub>MSR</sub> range dst[dsb...dsb+2<sup>ord</sup>-1] were revoked.
  - The parameters ca and sh were ignored.
- The permissions of each destination capability were masked by computing the logical AND of the permissions of the respective source capability and the permission mask pmm, i.e.
  - for bits set (1) in pmm, the respective permissions were *inherited* from the source capability.
  - for bits clear (0) in pmm, the respective permissions were *removed* for the destination capability.
- If the source capability was a Null Capability (CAP<sub>0</sub>) or if the destination capability has zero permissions after masking, then the destination capability is a Null Capability (CAP<sub>0</sub>).
- The resources for storing the granted capabilities were accounted to the PD to which the space referred to by SPC<sub>OBJCHREENT</sub>[dst] belongs.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### **BAD CAP**

 SPC<sub>OBJ<sub>CURRENT</sub></sub>[src] or SPC<sub>OBJ<sub>CURRENT</sub></sub>[dst] did not refer to compatible space capabilities or had insufficient permissions.

#### **BAD PAR**

- Capability Selector ssb or dsb was not order-aligned.
- Capability Selector ssb+2<sup>ord</sup>-1 or dsb+2<sup>ord</sup>-1 was larger than the maximum selector number.
- If src refers to a PIO Space or an MSR Space: Capability Selectors ssb and dsb were not equal.

#### MEM\_CAP

• The PD to which the space referred to by SPC<sub>OBJCURRENT</sub>[dst] belongs had insufficient memory resources for allocating the storage required for granting all destination capabilities. This constitutes a partial failure of the operation, because all destination capabilities up to the first allocation failure have been granted.

#### **5.4.2 Control Execution Context**

#### Parameters:

```
status = ctrl_ec (SELOBJ ec);  // Execution Context
```

#### Flags:

#### **Description:**

Prior to the hypercall:

• SPC<sub>OBJ<sub>CURRENT</sub></sub>[ec] must refer to an EC Capability (CAP<sub>OBJ<sub>EC</sub></sub>) with permission CTRL.

If the hypercall completed successfully:

- The EC referred to by SPC<sub>OBJ<sub>CURRENT</sub></sub>[ec] has been forced to enter the microhypervisor. It will generate a
  recall exception prior to its next exit from the microhypervisor and will traverse through the respective
  Event Portal (Arm, x86).
- If S=0 (Weak Recall):
  - The hypercall returns as soon as the recall exception has been *pended*, i.e. the EC may not have entered the microhypervisor yet.
- If S=1 (Strong Recall):
  - The hypercall returns as soon as the recall exception has been *observed*, i.e the EC will have entered the microhypervisor.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### **BAD CAP**

• SPC<sub>OBJ<sub>CURRENT</sub></sub>[ec] did not refer to an EC Capability (CAP<sub>OBJ<sub>EC</sub></sub>) or that capability had insufficient permissions.

## 5.4.3 Control Scheduling Context

#### Parameters:

#### Flags:

## Description:

Prior to the hypercall:

• SPC<sub>OBJ<sub>CURRENT</sub></sub>[sc] must refer to an SC Capability (CAP<sub>OBJ<sub>SC</sub></sub>) with permission CTRL.

If the hypercall completed successfully:

• The microhypervisor has returned the total consumed execution time as System Time Counter (STC) value for the SC referred to by SPC<sub>OBJ<sub>CURRENT</sub></sub>[sc].

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### BAD\_CAP

• SPC<sub>OBJ<sub>CURRENT</sub></sub>[sc] did not refer to an SC Capability (CAP<sub>OBJ<sub>SC</sub></sub>) or that capability had insufficient permissions.

#### 5.4.4 Control Portal

#### Parameters:

#### Flags:

#### **Description:**

Prior to the hypercall:

• SPC<sub>OBJ<sub>CURRENT</sub></sub> [pt] must refer to a PT Capability (CAP<sub>OBJ<sub>PT</sub></sub>) with permission CTRL.

If the hypercall completed successfully:

- The microhypervisor has set the Portal Identifier (PID) to pid and the Message Transfer Descriptor (MTD) to mtd for the Portal referred to by SPC<sub>OBJ<sub>CURRENT</sub></sub>[pt].
- Subsequent portal traversals will use the new MTD and return the new PID.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### **BAD CAP**

• SPC<sub>OBJ<sub>CURRENT</sub></sub>[pt] did not refer to a PT Capability (CAP<sub>OBJ<sub>PT</sub></sub>) or that capability had insufficient permissions.

#### 5.4.5 Control Semaphore

#### Parameters:

#### Flags:

#### **Description:**

Prior to the hypercall:

- If **D=0** (Semaphore Up):
  - SPC<sub>OBJCURRENT</sub>[sm] must refer to an SM Capability (CAP<sub>OBJSM</sub>) with permission CTRL<sub>UP</sub>.
- If D=1 (Semaphore Down):
  - SPC<sub>OBJ<sub>CURRENT</sub></sub>[sm] must refer to an SM Capability (CAP<sub>OBJ<sub>SM</sub></sub>) with permission CTRL<sub>DN</sub>.

If the hypercall completed successfully:

- If **D=0** (Semaphore Up):
  - If there were ECs blocked on the semaphore, then the microhypervisor has released one of those blocked ECs. Otherwise, the microhypervisor has incremented the semaphore counter. The timeout value and the Z-flag were ignored.
- If D=1 (Semaphore Down):
  - If the semaphore counter was larger than zero, then the microhypervisor has decremented the semaphore counter (Z=0) or set it to zero (Z=1). Otherwise, the microhypervisor has blocked EC<sub>CURRENT</sub> on the semaphore. If the timeout value was non-zero, EC<sub>CURRENT</sub> unblocks with a timeout status when the System Time Counter (STC) reaches or exceeds the specified value.

Blocking and releasing of ECs on a semaphore uses the FIFO queueing discipline.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### **TIMEOUT**

• If **D=1**: Down operation aborted when the timeout triggered.

#### **OVRFLOW**

• If **D=0**: Up operation aborted because the semaphore counter would overflow.

#### BAD\_CAP

 SPC<sub>OBJ<sub>CURRENT</sub></sub> [sm] did not refer to an SM Capability (CAP<sub>OBJ<sub>SM</sub></sub>) or that capability had insufficient permissions.

#### **BAD CPU**

• If **D=1** on an interrupt semaphore: Attempt to wait for the interrupt on a different CPU than the CPU to which that interrupt has been routed via assign\_int.

## 5.5 Platform Management

#### 5.5.1 Control Hardware

#### Parameters:

status = ctrl\_hw (UINT desc); // Descriptor

#### Flags:

#### **Description:**

Modifies the platform hardware configuration or power management state.

Prior to the hypercall:

- The hypercall must be invoked by an Execution Context in the Root Protection Domain (PD<sub>ROOT</sub>).
- If **OP=0** (S-State Transition):
  - The descriptor desc uses the following encoding:

The value S designates the platform-wide sleep or reset state that shall be entered. The values
 A and B are the first two bytes of the respective \\_Sx package in the ACPI root namespace as
 follows:

$\mathbf{S}$	A	В	Shallow	Description
0x1	\_S1[0]	\_S1[1]	<b>√</b>	S1: Stop Grant
0x2	\_S2[0]	\_S2[1]	$\checkmark$	S2: Power-On Suspend
0x3	\_S3[0]	\_S3[1]	$\checkmark$	S3: Suspend to RAM
0x4	\_S4[0]	\_S4[1]	×	S4: Suspend to Disk
0x5	\_S5[0]	\_S5[1]	×	S5: Soft Off
0x7	0x0	0x0	×	Platform Reset

- The caller is responsible for invoking the necessary pre-sleep ACPI methods, for transitioning platform devices into a suitable Dx sleep state, and for programming wakeup events.

#### • If **OP=4** (**QOS** Configuration):

- The descriptor desc uses the following encoding:

- Only Code and Data Prioritization (CDP) settings supported by the ambient CPU are valid.
  - \* The L3 bit disables (0) or enables (1) CDP<sub>L3</sub> on the ambient CPU.
  - \* The L2 bit disables (0) or enables (1) CDP<sub>L2</sub> on the ambient CPU.
- CAT/CDP or MBA settings cannot be configured for a CPU until a valid QOS configuration has been established for that CPU. Subsequently, that QOS configuration cannot be changed anymore.

#### • If OP=5 (CAT/CDP L3 Capacity Bitmask):

- The descriptor desc uses the following encoding:

	-	L3 Capacity Bitmask		N
55	48 47		16 15	5 0

- N designates the CPU-local Class Of Service (COS) that shall be configured. Only COS below COS<sub>L3</sub> of the ambient CPU are valid.
  - \* If CDP<sub>L3</sub> is disabled on the ambient CPU:
    - · To configure the CAT<sub>L3</sub> Capacity Bitmask for a COS, use N=COS.
  - \* If CDP<sub>L3</sub> is enabled on the ambient CPU:
    - · To configure the CDP<sub>L3-Data</sub> Capacity Bitmask for a COS, use N=(COS<<1).
    - · To configure the CDP<sub>L3-Code</sub> Capacity Bitmask for a COS, use N=(COS<<1)+1.
- For the L3 Capacity Bitmask, all (and only) contiguous combinations of 1-bits up to the highest capacity bit supported by the ambient CPU are valid.

#### • If OP=6 (CAT/CDP L2 Capacity Bitmask):

- The descriptor desc uses the following encoding:

- N designates the CPU-local Class Of Service (COS) that shall be configured. Only COS below COS<sub>1,2</sub> of the ambient CPU are valid.
  - \* If CDP<sub>L2</sub> is disabled on the ambient CPU:
    - · To configure the CAT<sub>L2</sub> Capacity Bitmask for a COS, use N=COS.
  - \* If CDP<sub>L2</sub> is enabled on the ambient CPU:
    - · To configure the CDP<sub>L2-Data</sub> Capacity Bitmask for a COS, use N=(COS<<1).
    - · To configure the CDP<sub>L2-Code</sub> Capacity Bitmask for a COS, use N=(COS<<1)+1.
- For the L2 Capacity Bitmask, all (and only) contiguous combinations of 1-bits up to the highest capacity bit supported by the ambient CPU are valid.

#### • If **OP=7** (**MBA Delay**):

- The descriptor desc uses the following encoding:

- COS designates the CPU-local Class Of Service (COS) that shall be configured. Only COS below COS<sub>MB</sub> of the ambient CPU are valid.
- For the MBA Delay, only values up to the highest delay supported by the ambient CPU are valid.

If the hypercall completed successfully:

#### • If **OP=0** (S-State Transition):

- The platform enters the specified ACPI sleep state or resets.
- For shallow sleep states, the hypercall returns upon a wakeup event. The caller is responsible for invoking the necessary post-sleep ACPI methods and for transitioning platform devices back into the D0 working state.
- For deep sleep states or platform reset, the hypercall does not return.

#### • If **OP=4** (**QOS** Configuration):

- The ambient CPU uses and locks down the QOS configuration.

#### • If OP=5 (CAT/CDP L3 Capacity Bitmask):

- The ambient CPU uses the L3 Capacity Bitmask for the designated COS.

#### • If OP=6 (CAT/CDP L2 Capacity Bitmask):

- The ambient CPU uses the L2 Capacity Bitmask for the designated COS.
- If **OP=7** (**MBA Delay**):
  - The ambient CPU uses the MBA Delay for the designated COS.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### BAD\_HYP

• The hypercall was not invoked from the Root Protection Domain (PD<sub>ROOT</sub>).

#### BAD\_FTR

• The requested feature is not supported by the platform.

#### BAD\_PAR

- If **OP=4**: The **QOS** configuration is invalid.
- If OP=5/6/7: The COS, CAT/CDP capacity bitmask or MBA delay is invalid.
- Otherwise: The requested operation (OP) is invalid.

#### **ABORTED**

- If **OP=0**: A concurrent power management transition prevailed.
- If **OP=4**: A **QOS** configuration has already been established for the ambient **CPU**.
- If OP=5/6/7: A QOS configuration has not yet been established for the ambient CPU.

#### 5.5.2 Assign Interrupt

#### Parameters:

#### Flags:

G	P	T	M
3	2	1	0

#### **Description:**

Configures an interrupt and routes it to the specified CPU.

Prior to the hypercall:

- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sm] must refer to an SM Capability (CAP<sub>OBJ<sub>SM</sub></sub>) with permission ASSIGN.
- CAP<sub>OBJ<sub>SM</sub></sub> must refer to an interrupt semaphore and thereby designates the interrupt.

If the hypercall completed successfully:

- The interrupt referred to by SPC<sub>OBJCURRENT</sub>[sm] has been routed to the CPU cpu.
- Mask
  - M=0: The interrupt is now unmasked, i.e. it will be signaled on the semaphore.
  - M=1: The interrupt is now masked, i.e. it will not be signaled on the semaphore.
- Trigger
  - T=0: The interrupt is now configured for edge-triggered operation.
  - T=1: The interrupt is now configured for level-triggered operation.
- Polarity
  - **P=0**: The interrupt is now configured for active-high operation.
  - P=1: The interrupt is now configured for active-low operation.
- Guest
  - **G=0**: The interrupt is now host-owned.
  - G=1: The interrupt is now guest-owned (VM pass-through).
- If the interrupt is an MSI, only the PCI device referred to by dev will be authorized to generate that MSI. The device driver must program the returned msi\_addr and msi\_data values into the MSI registers of that device to ensure proper interrupt operation. If the interrupt is pin-based, the parameter dev was ignored and the parameters msi\_addr and msi\_data return 0.

Prior to the first invocation of assign\_int for an interrupt, the state of that interrupt is as follows:

- the interrupt is masked.
- trigger, polarity and ownership are undefined.
- target CPU and authorized device are undefined.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### **BAD CPU**

• The specified CPU number was invalid.

## BAD\_CAP

- SPC<sub>OBJ<sub>CURRENT</sub></sub>[sm] did not refer to an SM Capability (CAP<sub>OBJ<sub>SM</sub></sub>) or that capability had insufficient permissions.
- CAP<sub>OBJ<sub>SM</sub></sub> did not refer to an interrupt semaphore.

#### 5.5.3 Assign Device

#### Parameters:

#### Flags:

#### **Description:**

Assigns a device to the specified DMA Space.

Prior to the hypercall:

- The hypercall must be invoked by an Execution Context in the Root Protection Domain (PD<sub>ROOT</sub>).
- SPC<sub>OBJ<sub>CURRENT</sub></sub> [dma] must refer to a DMA Space Capability (CAP<sub>OBJ<sub>DMA</sub></sub>) with permission ASSIGN.
- The parameter smmu designates the SMMU/IOMMU via its physical address.
- DAD designates the device and SMMU resources to use for managing that device.

If the hypercall completed successfully:

- The device designated by DAD has been assigned to the DMA Space referred to by SPC<sub>OBJCURRENT</sub> [dma].
- DMA transactions of that device will be managed using the SMMU resources encoded in DAD. Prior users of those SMMU resources have been unconfigured.

#### Status:

#### **SUCCESS**

• The hypercall completed successfully.

#### **BAD HYP**

• The hypercall was not invoked from the Root Protection Domain (PD<sub>ROOT</sub>).

#### **BAD DEV**

• The parameter smmu did not refer to the physical address of an SMMU device.

#### BAD\_CAP

• SPC<sub>OBJ<sub>CURRENT</sub></sub>[dma] did not refer to a DMA Space Capability (CAP<sub>OBJ<sub>DMA</sub></sub>) or that capability had insufficient permissions.

#### BAD\_PAR

• The parameter dad was invalid.

# 6 Booting

# 6.1 Microhypervisor

#### 6.1.1 NOVA ELF Image

The bootloader must place all loadable (PT\_LOAD) program segments of the NOVA microhypervisor into physical memory (RAM) according to the physical addresses (p\_paddr) and memory sizes (p\_memsz) defined in the NOVA microhypervisor ELF image. The following is an example:

```
readelf -l nova.elf
```

Elf file type is EXEC (Executable file)

#### Entry point 0x48000000

There are 2 program headers, starting at offset 64

#### Program Headers:

Type	Offset	VirtAddr	PhysAdo	ir
	FileSiz	MemSiz	Flags	Align
LOAD	0x000000000000000b0	0x0000000048000000	0x00000	000048000000
	0x00000000000000268	0x000000000001000	RWE	0x8
LOAD	0x000000000000000000000000000000000000	0x0000ff8000001000	0x00000	000048001000
	0x0000000000000e960	0x0000000000fff000	RWE	0x800

If the physical address range defined in the ELF image is suboptimal for a particular platform, the bootloader may shift all loadable program segments lower or higher in physical memory, by applying an offset, subject to the following constraints:

- The same offset must be applied to each loadable program segment and to the entry point.
- The offset must be a multiple of 2 MiB, i.e.  $PhysAddr_{NEW} = PhysAddr_{ELF} \pm n \times 2 MiB$ .
- The entire physical memory region occupied by the NOVA microhypervisor must be RAM.

After loading the NOVA microhypervisor into physical memory, the bootloader must invoke the entry point of the ELF image with architecture-specific preconditions (Arm, x86).

#### 6.1.2 NOVA Object Space

The NOVA Object Space (SPC<sub>OBJ<sub>NOVA</sub></sub>) contains the following CAP<sub>OBJ</sub>:

$SEL_{OBJ}$	Capability Type	Capability Resource	<b>Capability Permissions</b>
SEL <sub>NUM</sub> -1	$CAP_{OBJ_{SM}}$	Console Semaphore	All defined permissions
SEL <sub>NUM</sub> -2	$CAP_{OBJ_{OBJ}}$	NOVA Object Space	TAKE
SEL <sub>NUM</sub> -3	$CAP_{OBJ_{HST}}$	NOVA Host Space	TAKE
SEL <sub>NUM</sub> -4	$CAP_{OBJ_{PIO}}$	NOVA PIO Space <sup>†</sup>	TAKE
SEL <sub>NUM</sub> -5	$CAP_{OBJ_{MSR}}$	NOVA MSR Space <sup>†</sup>	TAKE
SEL <sub>NUM</sub> -6	$CAP_{OBJ_{OBJ}}$	Root Object Space	All defined permissions
SEL <sub>NUM</sub> -7	$CAP_{OBJ_{HST}}$	Root Host Space	All defined permissions
SEL <sub>NUM</sub> -8	$CAP_{OBJ_{PIO}}$	Root PIO Space <sup>†</sup>	All defined permissions
$2^{16} \dots 2^{16} + INT_{PIN} + INT_{MSI} - 1$	$CAP_{OBJ_{SM}}$	Interrupt Semaphores	ASSIGN, CTRL <sub>DN</sub>
0CPU <sub>NUM</sub> - 1	$CAP_{OBJ_{SC}}$	Idle Scheduling Contexts	CTRL

Using SPC<sub>OBJ<sub>NOVA</sub></sub> as source space for the ctrl\_pd hypercall facilitates the delegation of CAP<sub>OBJ</sub> from the NOVA Object Space to another Object Space.

#### 6.1.3 NOVA Host Space

In the NOVA Host Space (SPC<sub>HST<sub>NOVA</sub></sub>), SEL<sub>HST</sub> N refers to

- CAP<sub>0</sub> for memory protected by the NOVA microhypervisor (Arm, x86).
- CAP<sub>MEM</sub> for the 4 KiB page frame at **physical** address N << 12 with all defined permissions otherwise.

Using SPC<sub>HST<sub>NOVA</sub></sub> as source space for the ctrl\_pd hypercall facilitates the delegation of CAP<sub>MEM</sub> from the NOVA Host Space to another Host Space, Guest Space or DMA Space.

#### 6.1.4 NOVA PIO Space

In the NOVA PIO Space (SPC<sub>PIONOVA</sub>), SEL<sub>PIO</sub> N refers to

- CAP<sub>0</sub> for an I/O port protected by the NOVA microhypervisor (x86).
- CAP<sub>PIO</sub> for the I/O port number N with all defined permissions otherwise.

Using SPC<sub>PIONOVA</sub> as source space for the ctrl\_pd hypercall facilitates the delegation of CAP<sub>PIO</sub> from the NOVA PIO Space to another PIO Space.

#### 6.1.5 NOVA MSR Space

In the NOVA MSR Space (SPC<sub>MSR<sub>NOVA</sub></sub>), SEL<sub>MSR</sub> N refers to

- CAP<sub>0</sub> for an MSR protected by the NOVA microhypervisor (x86).
- CAP<sub>MSR</sub> for the MSR number N with all defined permissions otherwise.

Using SPC<sub>MSR<sub>NOVA</sub></sub> as source space for the ctrl\_pd hypercall facilitates the delegation of CAP<sub>MSR</sub> from the NOVA MSR Space to another MSR Space.

<sup>&</sup>lt;sup>†</sup>Only on architectures, where this type of space exists, otherwise Null Capability (CAP<sub>0</sub>).

#### 6.2 Root Protection Domain

After the NOVA microhypervisor has initialized the system, it creates the following initial kernel objects:

- Root Protection Domain (PD<sub>ROOT</sub>)
  - with Root Object Space (SPC<sub>OBJROOT</sub>)
  - with Root Host Space (SPC<sub>HST<sub>ROOT</sub></sub>)
  - with Root PIO Space (SPC<sub>PIOROOT</sub>)<sup>†</sup>
- Root Execution Context (EC<sub>ROOT</sub>) on CPU<sub>BSP</sub>
  - bound to SPC<sub>OBJ<sub>ROOT</sub></sub>, SPC<sub>HST<sub>ROOT</sub></sub>, SPC<sub>PIO<sub>ROOT</sub></sub> †
  - with  $SEL_{EVT} = 0$
- Root Scheduling Context (SC<sub>ROOT</sub>) on CPU<sub>BSP</sub>
  - bound to EC<sub>ROOT</sub>
  - with COS = 0
  - with Priority = highest priority
  - with Budget = 1000 ms

The Root Protection Domain is responsible for bootstrapping the other components of the user-mode framework by creating additional kernel objects, loading additional images, assigning resources, etc.

#### 6.2.1 Root ELF Image

The ELF image of the Root Protection Domain (PD<sub>ROOT</sub>) must be an executable (ET\_EXEC) file that has been compiled for the respective architecture and

- linked such that p\_filesz = p\_memsz
- loaded such that p\_vaddr ≡ LOAD\_ADDR\* + p\_offset (mod PAGE\_SIZE)

holds for each loadable (PT\_LOAD) program segment. These constraints ensure that the NOVA microhypervisor can map all program segments directly from physical into virtual memory without any additional memory allocation or copying. The following is an example:

```
readelf -1 root.elf
```

```
Elf file type is EXEC (Executable file)
Entry point 0x10000120
There are 2 program headers, starting at offset 64
```

# Program Headers:

rogram ne	uuci bi		
Type	Offset	VirtAddr	PhysAddr
	FileSiz	MemSiz	Flags Align
LOAD	0x0000000000000000	0 0x0000000010000000	0x000000010000000
	0x00000000000000a75	0x000000000000000a75	R E 0x1000
LOAD	0x0000000000001000	0 0x0000000010001000	0x0000000010001000
	0x000000000000f004	1 0x000000000000f004	RW 0x1000

Prior to the Root Execution Context ( $EC_{ROOT}$ ) invoking the entry point of the Root Protection Domain ( $PD_{ROOT}$ ) ELF image, the NOVA microhypervisor sets up the spaces for  $PD_{ROOT}$  as described in the following subsections.

<sup>&</sup>lt;sup>†</sup>Only on architectures, where this type of space exists.

<sup>\*</sup>This is the address in physical memory at which the bootloader has placed the ELF image.

#### 6.2.2 Root Object Space

The Root Object Space (SPC<sub>OBJROOT</sub>) contains the following initial CAP<sub>OBJ</sub>:

<b>SEL<sub>OBJ</sub></b>	Capability Type	Capability Resource	<b>Capability Permissions</b>
SEL <sub>NUM</sub> -1	$CAP_{OBJ_{OBJ}}$	NOVA Object Space	TAKE
SEL <sub>NUM</sub> -2	$CAP_{OBJ_{OBJ}}$	Root Object Space	All defined permissions
SEL <sub>NUM</sub> -3	$CAP_{OBJ_{PD}}$	Root Protection Domain	All defined permissions
SEL <sub>NUM</sub> -4	$CAP_{OBJ_{EC}}$	Root Execution Context	All defined permissions
SEL <sub>NUM</sub> -5	$CAP_{OBJ_{SC}}$	Root Scheduling Context	All defined permissions

All other SEL<sub>OBJ</sub> in SPC<sub>OBJROOT</sub> initially refer to a Null Capability (CAP<sub>0</sub>).

#### 6.2.3 Root Host Space

#### **ELF Program Segments**

The microhypervisor maps the Root Protection Domain ( $PD_{ROOT}$ ) into the Root Host Space according to the virtual addresses ( $p_vaddr$ ), memory sizes ( $p_memsz$ ) and page attributes ( $p_flags$ ) of all loadable ( $PT_LOAD$ ) program segments defined in the  $PD_{ROOT}$  ELF image.

#### **Hypervisor Information Page**

The microhypervisor maps the Hypervisor Information Page read-only into the Root Host Space 4 KiB below the end of user-accessible virtual memory. The virtual address of the HIP is passed to  $EC_{ROOT}$  at the entry point (Arm, x86).

#### **UTCB**

The microhypervisor maps the User Thread Control Block of EC<sub>ROOT</sub> into the Root Host Space 4 KiB below the address of the Hypervisor Information Page.

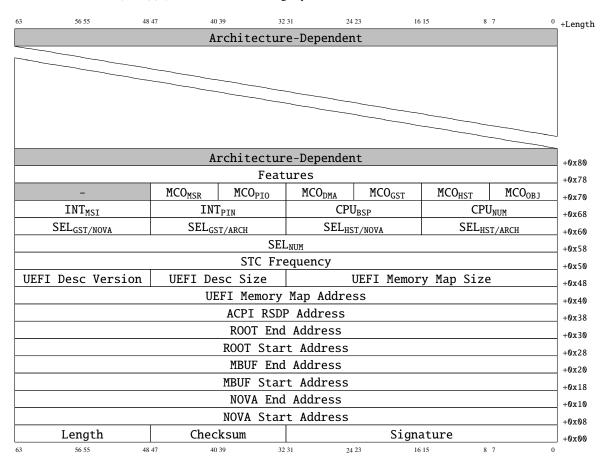

All other SEL<sub>HST</sub> in SPC<sub>HST<sub>ROOT</sub></sub> initially refer to a Null Capability (CAP<sub>0</sub>).

#### 6.2.4 Root PIO Space

All  $SEL_{PIO}$  in  $SPC_{PIO_{ROOT}}$  initially refer to a Null Capability (CAP<sub>0</sub>).

# 6.3 Hypervisor Information Page

The Hypervisor Information Page (HIP) conveys information about the platform and configuration to the Root Protection Domain (PD<sub>ROOT</sub>) and has the following layout:

All HIP fields are unsigned values, unless stated otherwise, and have the following meaning:

#### Signature

The value 0x41564f4e identifies the NOVA microhypervisor.

#### Checksum

The checksum is valid if 16bit-wise addition of the entire HIP contents produces a value of 0.

#### Length

Length of the entire HIP in bytes.

#### **NOVA Start/End Address**

Physical start and end address of the NOVA microhypervisor image.

#### **MBUF Start/End Address**

Physical start and end address of the memory buffer console region (see C.1).

#### **ROOT Start/End Address**

Physical start and end address of the root protection domain image.

#### **ACPI RSDP Address**

#### **UEFI Memory Map Address**

Physical address of the UEFI [7] Memory Map (0xfffffffffffffffff if not present).

#### **UEFI Memory Map Size**

Total size of the **UEFI** Memory Map (0 if not present).

#### **UEFI Desc Size**

**UEFI** Memory Descriptor Size (0 if not present).

#### **UEFI Desc Version**

**UEFI** Memory Descriptor Version (0 if not present).

#### **STC Frequency**

Frequency of the System Time Counter (STC) in Hz.

#### **SEL<sub>NUM</sub>**

Total number of Capability Selectors in each object space.

#### SEL<sub>HST/ARCH</sub>

Number of Capability Selectors required for handling architectual host events. (Arm, x86)

#### **SEL**<sub>HST/NOVA</sub>

Number of additional Capability Selectors required for handling microhypervisor host events. (Arm, x86)

#### SELCSTARCH

Number of Capability Selectors required for handling architectual guest events. (Arm, x86)

#### SEL<sub>GST/NOVA</sub>

Number of additional Capability Selectors required for handling microhypervisor guest events. (Arm, x86)

#### **CPU<sub>NUM</sub>**

Total number of CPUs that are online.

#### **CPU<sub>BSP</sub>**

The Bootstrap Processor (BSP) on which EC<sub>ROOT</sub> and SC<sub>ROOT</sub> have been created.

#### INT<sub>PIN</sub>

Total number of pin-signaled interrupts that can be used via interrupt semaphores.

#### $INT_{MSI}$

Total number of message-signaled interrupts that can be used via interrupt semaphores.

#### MCO<sub>OBJ</sub>

Maximum contiguous order that avoids partial failures during capability updates in SPC<sub>OBJ</sub>.

#### MCO<sub>HST</sub>

Maximum contiguous order that avoids partial failures during capability updates in SPC<sub>HST</sub>.

#### MCOGST

Maximum contiguous order that avoids partial failures during capability updates in SPC<sub>GST</sub>.

#### MCODMA

Maximum contiguous order that avoids partial failures during capability updates in SPC<sub>DMA</sub>.

#### MCO<sub>PIO</sub>

Maximum contiguous order that avoids partial failures during capability updates in SPCPIO.

#### $MCO_{MSR}$

Maximum contiguous order that avoids partial failures during capability updates in SPC<sub>MSR</sub>.

#### **Features**

Supported platform features.

#### **Architecture-Dependent**

Architecture-dependent part. (Arm, x86)

# Part IV Application Binary Interface

# 7 ABI aarch64

#### 7.1 Boot State

#### 7.1.1 NOVA Microhypervisor

The bootloader must set up the CPU register state according to one of the launch types listed below when it transfers control to the NOVA microhypervisor entry point. Furthermore, the following preconditions must be satisfied:

- The CPU must execute in EL2 (hypervisor mode) or in EL3 (monitor mode).
- Paging (MMU) must be disabled (SCTLR\_ELx.M=0) or must use an identity (1:1) mapping.
- Interrupts must be disabled (PSTATE.DAIF=0b1111).
- The physical memory region occupied by the microhypervisor image must be clean to the PoC.
- All DMA activity targeting the physical memory region occupied by the microhypervisor must be quiesced. That physical memory region should also be protected against DMA accesses on systems with an SMMU.

#### 7.1.1.1 Multiboot v2 Launch

Only this launch type supports 64-bit UEFI platforms.

Register	Value / Description
IP	Physical address of the NOVA ELF image entry point
X0	Multiboot v2 magic value (0x36d76289) [8]
X1	Physical address of the Multiboot v2 information structure [8]
0ther	<b>≁</b>

The NOVA microhypervisor consumes the following multiboot tags, if present: 1, 3, 12, 20.

#### 7.1.1.2 Multiboot v1 Launch

Register	Value / Description
IP	Physical address of the NOVA ELF image entry point
X0	Multiboot v1 magic value (0x2badb002) [9]
X1	Physical address of the Multiboot v1 information structure [9]
Other	*

The NOVA microhypervisor consumes the following multiboot flags, if present: 2, 3.

#### 7.1.1.3 Legacy Launch

Register	Value / Description
IP	Physical address of the NOVA ELF image entry point
X0	Physical address of the Flattened Device Tree (FDT) for the hardware platform <sup>†</sup>
X1	Physical address of the Root Protection Domain (PD <sub>ROOT</sub> ) ELF image
Other	*

<sup>&</sup>lt;sup>†</sup>Due to its alignment constraint, a valid FDT address will never be equal to a Multiboot magic value.

# 7.1.2 Root Protection Domain

The NOVA microhypervisor sets up the CPU register state as follows when it transfers control to the Root Execution Context ( $EC_{ROOT}$ ):

Register	Value / Description
IP	Virtual address of the Root Protection Domain (PD <sub>ROOT</sub> ) ELF image entry point
SP	Virtual address of the Hypervisor Information Page (HIP)
X0	X0 at boot time †
X1	X1 at boot time †
X2	X2 at boot time †
Other	*

 $<sup>^{\</sup>dagger}$ The register contains the preserved original value from the point when control was transferred from the bootloader to the microhypervisor.

#### 7.2 Protected Resources

The following resources are protected by the NOVA microhypervisor and are therefore inaccessible to user-mode applications.

#### **7.2.1 Memory**

Physical memory regions occupied by:

- NOVA microhypervisor conveyed via HIP.
- GICD, GICR, GICC, GICH devices [10, 11] conveyed via ACPI MADT or via FDT.
- SMMU devices [12, 13] conveyed via ACPI IORT or via FDT.
- Firmware runtime services conveyed via UEFI memory map.

# 7.3 Physical Memory

#### 7.3.1 Memory Map

The Root Protection Domain (PD<sub>ROOT</sub>) can obtain a list of available/reserved memory regions as follows:

- On platforms using Unified Extensible Firmware Interface, by parsing the UEFI memory map.
- On platforms using Flattened Device Tree, by parsing the FDT.

# 7.4 Virtual Memory

#### 7.4.1 Host-Virtual Addresses

Depending on the MMU features supported by the hardware platform, the Host-Virtual Address (HVA) range accessible to Host Execution Contexts is  $0 \le \text{HVA} < 2^H$  with  $32 \le H \le 52$ .

The Root Protection Domain (PD<sub>ROOT</sub>) should determine 2<sup>H</sup> based on the virtual address of the HIP.

#### 7.4.2 Guest-Physical Addresses

Depending on the MMU features supported by the hardware platform, the Guest-Physical Address (GPA) range accessible to Guest Execution Contexts is  $0 \le \text{GPA} < 2^G$  with  $32 \le G \le 52$  and G = H.

# 7.4.3 Cacheability Attributes

Encoding	ATTR <sub>CA</sub>	Description
0x0	DEV	Device
0x1	DEV_E	Device, Early Ack
0x2	DEV_RE	Device, Early Ack, Reordering
0x3	DEV_GRE	Device, Early Ack, Reordering, Gathering
0x4	-	reserved
0x5	MEM_NC	Memory, Inner/Outer Non-Cacheable
0x6	MEM_WT	Memory, Inner/Outer Write-Through
0x7	MEM_WB	Memory, Inner/Outer Write-Back

Please refer to [3] for details on the architectural behavior.

# 7.4.4 Shareability Attributes

Encoding	$ATTR_{SH}$	Description
0x0	NONE	Not Shareable
0x1	=	reserved
0x2	OUTER	Outer Shareable
0x3	INNER	Inner Shareable

Please refer to [3] for details on the architectural behavior.

# 7.5 Class Of Service

Class Of Service (COS) is currently not supported.

# 7.6 Event-Specific Capability Selectors

For the delivery of exception/intercept messages, the microhypervisor performs an implicit portal traversal.

The selector for the destination portal (SEL<sub>OBJ</sub>):

- is determined by adding the exception/intercept number to the affected Execution Context's Event Selector Base (SEL<sub>EVT</sub>).
- indexes into the Object Space (SPC<sub>OBJ</sub>) of the affected EC's Protection Domain (PD).
- must refer to a PT Capability (CAP<sub>OBJPT</sub>) with permission EVENT that is bound to an EC on the same core as the affected EC, otherwise the affected EC is killed.

#### 7.6.1 Architectural Events

#### **Host Exceptions and Guest Intercepts**

SEL <sub>OBJ</sub>	Exception / Intercept	$SEL_{OBJ}$	Exception / Intercept
$SEL_{EVT} + 0x00$	Unknown Reason	SEL <sub>EVT</sub> + 0x20	Instruction Abort (lower EL)
$SEL_{EVT} + 0x01$	Trapped WFI or WFE	$SEL_{EVT} + 0x21$	Instruction Abort (same EL)*
$SEL_{EVT} + 0x02$	reserved	$SEL_{EVT} + 0x22$	PC Alignment Fault
$SEL_{EVT} + 0x03$	Trapped MCR or MRC	$SEL_{EVT} + 0x23$	reserved
$SEL_{EVT} + 0x04$	Trapped MCRR or MRRC	$SEL_{EVT} + 0x24$	Data Abort (lower EL)
$SEL_{EVT} + 0x05$	Trapped MCR or MRC	$SEL_{EVT} + 0x25$	Data Abort (same EL)*
$SEL_{EVT} + 0x06$	Trapped LDC or STC	$SEL_{EVT} + 0x26$	SP Alignment Fault
$SEL_{EVT} + 0x07$	SME, SVE, SIMD, FPU	$SEL_{EVT} + 0x27$	Memory Operation Exception
$SEL_{EVT} + 0x08$	Trapped VMRS Access	$SEL_{EVT} + 0x28$	Trapped FPU (AArch32)
$SEL_{EVT} + 0x09$	Trapped PAuth Instruction	$SEL_{EVT} + 0x29$	reserved
$SEL_{EVT} + 0x0a$	Trapped LD64B or ST64B	$SEL_{EVT} + 0x2a$	reserved
$SEL_{EVT} + 0x0b$	reserved	$SEL_{EVT} + 0x2b$	reserved
$SEL_{EVT} + 0x0c$	Trapped MRRC	$SEL_{EVT} + 0x2c$	Trapped FPU (AArch64)
$SEL_{EVT} + 0x0d$	Branch Target Exception	$SEL_{EVT} + 0x2d$	reserved
$SEL_{EVT} + 0x0e$	Illegal Execution State	$SEL_{EVT} + 0x2e$	reserved
$SEL_{EVT} + 0x0f$	reserved	$SEL_{EVT} + 0x2f$	SError
$SEL_{EVT} + 0x10$	reserved	$SEL_{EVT} + 0x30$	Breakpoint (lower EL)
$SEL_{EVT} + 0x11$	SVC (from AArch32 State)	$SEL_{EVT} + 0x31$	Breakpoint (same EL)*
$SEL_{EVT} + 0x12$	HVC (from AArch32 State)	$SEL_{EVT} + 0x32$	Software Step (lower EL)
$SEL_{EVT} + 0x13$	SMC (from AArch32 State)	$SEL_{EVT} + 0x33$	Software Step (same EL)*
$SEL_{EVT} + 0x14$	reserved	$SEL_{EVT} + 0x34$	Watchpoint (lower EL)
$SEL_{EVT} + 0x15$	SVC (from AArch64 State)*	$SEL_{EVT} + 0x35$	Watchpoint (same EL)*
$SEL_{EVT} + 0x16$	HVC (from AArch64 State)	$SEL_{EVT} + 0x36$	reserved
$SEL_{EVT} + 0x17$	SMC (from AArch64 State)	$SEL_{EVT} + 0x37$	reserved
$SEL_{EVT} + 0x18$	Trapped MSR or MRS	$SEL_{EVT} + 0x38$	BKPT (AArch32)
$SEL_{EVT} + 0x19$	Trapped SVE	$SEL_{EVT} + 0x39$	reserved
$SEL_{EVT} + 0x1a$	Trapped ERET	$SEL_{EVT} + 0x3a$	Vector Catch (AArch32)
$SEL_{EVT} + 0x1b$	TSTART Exception	$SEL_{EVT} + 0x3b$	reserved
$SEL_{EVT} + 0x1c$	PAuth Instruction Failure	$SEL_{EVT} + 0x3c$	BRK (AArch64)
$SEL_{EVT} + 0x1d$	Trapped SME	$SEL_{EVT} + 0x3d$	reserved
$SEL_{EVT} + 0x1e$	Granule Protection Exception	$SEL_{EVT} + 0x3e$	reserved
$SEL_{EVT} + 0x1f$	reserved	$SEL_{EVT} + 0x3f$	reserved

Please refer to [3] for more details on each of these events.

<sup>\*</sup>These events may be handled by the microhypervisor, in which case they will not cause portal traversals.

# 7.6.2 Microhypervisor Events

SEL <sub>OBJ</sub>	Event
SEL <sub>EVT</sub> + SEL <sub>ARCH</sub> + 0x0	Startup
$SEL_{EVT} + SEL_{ARCH} + 0x1$	Recall
$SEL_{EVT} + SEL_{ARCH} + 0x2$	Virtual Timer

The value of  $\mathsf{SEL}_{\mathtt{ARCH}}$  depends on the origin of the event:

- $SEL_{ARCH} = SEL_{HST/ARCH}$  for events that occurred in the host.
- SEL<sub>ARCH</sub> = SEL<sub>GST/ARCH</sub> for events that occurred in the guest.

# 7.7 Architecture-Dependent Structures

## 7.7.3 Message Transfer Descriptor

The Message Transfer Descriptor (MTD), which controls the subset of the architectural state transferred during exceptions and intercepts, as described in Section 4.4.2, has the following layout:

Each MTD bit controls the transfer of the listed architectural state to/from the respective fields in the UTCB (7.7.2) as follows:

- State with access r can be read from the architectural state into the UTCB.
- State with access w can be written from the UTCB into the architectural state.

MTD Bit	Access	<b>Host Execution Context State</b>	<b>Guest Execution Context State</b>
POISON	W	Kills the EC <sub>HST</sub>	Kills the EC <sub>GST</sub>
ICI <sup>†</sup>	W	Invalidates the entire I-Cache	Invalidates the entire I-Cache

SPACES	W	-	SEL_GST

<sup>\*</sup>Only the condition flags are writable.

<sup>†</sup>Only affects a VIPT instruction cache of the local core. Has no effect on PIPT instruction caches, data caches, or caches of other cores.

#### 7.7.4 Device Assignment Descriptor

The Device Assignment Descriptor (DAD) describes a device to be assigned to a DMA Space ( $SPC_{DMA}$ ). On Arm, it also specifies the SMMU resources that should be used to manage DMA transactions of that device.

The fields are defined as follows:

#### SID

Designates the device via its Stream Identifier (SID).

#### **SID Mask**

Specifies which bits of that SID should be matched (0) or ignored (1) by the Stream Mapping Group.

#### SMG

Specifies the Stream Mapping Group (SMG) to use for that SID – must be < SMG $_{NUM}$ .

#### CTX

Specifies the Translation Context (CTX) to use for that SMG – must be  $< CTX_{NUM}$ .

System software must ensure an unambiguous assignment of Stream Identifiers to Stream Mapping Groups, i.e. it must configure the SID/Mask fields across all Stream Mapping Groups such that no SID multi-matches can occur.

# 7.8 Calling Convention

The following pages describes the calling convention for each hypercall. A Host Execution Context calls into the microhypervisor by loading the hypercall identifier and other parameters into the specified CPU registers and then executes the svc #0 instruction [3].

The hypercall identifier consists of the hypercall number and hypercall-specific flags, as illustrated in Figure 7.1.

Figure 7.1: Hypercall Identifier

The status code returned from a hypercall has the format shown in Figure 7.2.

Figure 7.2: Status Code

The assignment of hypercall parameters to CPU registers is shown on the left side, the contents of the CPU registers after the hypercall is shown on the right side.

#### **IPC Call**

#### **IPC Reply**

#### **Create Protection Domain**

#### **Create Execution Context**

#### **Create Scheduling Context**

#### **Create Portal**

#### **Create Semaphore**

#### **Control Protection Domain**

#### **Control Execution Context**

$$\begin{array}{c|cccc} ec_{[63-8]} & hypercall_{[7-0]} & \verb"X0" & \hline & \verb"ctrl_ec" & \verb"X0" & status_{[7-0]} \\ & - & IP & svc \#0 & IP & IP+4 \\ \end{array}$$

#### **Control Scheduling Context**

#### **Control Portal**

#### **Control Semaphore**

#### **Control Hardware**

#### **Assign Interrupt**

#### **Assign Device**

# 7.9 Supplementary Functionality

This section describes functions that do **not** conform to the calling convention for hypercalls. Because these functions cannot perform capability-based access control, their invocation is restricted to the Root Protection Domain (PD<sub>ROOT</sub>). Invocation of these functions from any other Protection Domain generates an exception.

#### **Secure Monitor Call**

		proxy_smc		
$identifier_{[31-0]}$	X0	<u> </u>	X0	~
_	X1		X1	~
_	X2		X2	~
_	Х3		Х3	~
_	X4		X4	~
_	X5		<b>X</b> 5	~
_	Х6		Х6	~
_	X7		Х7	~
_	X8		Х8	~
-	Х9		Х9	~
-	X10		X10	~
-	X11		X11	~
-	X12		X12	~
-	X13		X13	~
-	X14		X14	~
-	X15		X15	~
-	X16		X16	~
-	X17		X17	~
-	IP	svc #1	IP	IP+4

This call is proxy-filtered by the microhypervisor. If the combination of invoked service (identifier $_{[29-24]}$ ) and function (identifier $_{[15-0]}$ ) is listed in the table below, then the microhypervisor issues the corresponding SMC to platform firmware on behalf of the caller. Otherwise, this function generates an exception. Register allocation conforms to the Arm SMCCC [14].

Service	Description	Function	Description
0x2	SIP Service Calls	0x0000-0xffff	All functions
0x4	Standard Secure Service Calls	0x0050-0x005f	TRNG functions [15]
0.44		0x0130-0x013f	PCI functions [16]
0x30-0x31	Trusted Application Calls	0x0000-0xffff	All functions
0x32-0x3f	Trusted OS Calls	0x0000-0xffff	All functions

# 8 ABI x86-64

#### 8.1 Boot State

#### 8.1.1 NOVA Microhypervisor

The bootloader must set up the CPU register state according to one of the launch types listed below when it transfers control to the NOVA microhypervisor entry point. Furthermore, the following preconditions must be satisfied:

- The CPU state must conform to a machine state defined in the Multiboot Specification v2 [8] or v1 [9].
- All DMA activity targeting the physical memory region occupied by the microhypervisor must be quiesced. That physical memory region should also be protected against DMA accesses on systems with an IOMMU.

#### 8.1.1.1 Multiboot v2 Launch

Only this launch type supports 64-bit UEFI platforms.

Register	Value / Description
EIP	Physical address of the NOVA ELF image entry point
EAX	Multiboot v2 magic value (0x36d76289) [8]
EBX	Physical address of the Multiboot v2 information structure [8]
0ther	*

The NOVA microhypervisor consumes the following multiboot tags, if present: 1, 3, 12, 20.

#### 8.1.1.2 Multiboot v1 Launch

Register	Value / Description
EIP	Physical address of the NOVA ELF image entry point
EAX	Multiboot v1 magic value (0x2badb002) [9]
EBX	Physical address of the Multiboot v1 information structure [9]
Other	<b>≁</b>

The NOVA microhypervisor consumes the following multiboot flags, if present: 2, 3.

#### 8.1.2 Root Protection Domain

The NOVA microhypervisor sets up the CPU register state as follows when it transfers control to the Root Execution Context (EC<sub>ROOT</sub>):

Register	Value / Description
RIP	Virtual address of the Root Protection Domain (PD <sub>ROOT</sub> ) ELF image entry point
RSP	Virtual address of the Hypervisor Information Page (HIP)
RDI	EAX at boot time †
RSI	EBX at boot time †
Other	*

<sup>†</sup>The register contains the preserved original value from the point when control was transferred from the bootloader to the microhypervisor.

#### 8.2 Protected Resources

The following resources are protected by the NOVA microhypervisor and are therefore inaccessible to user-mode applications.

#### 8.2.1 Memory

Physical memory regions occupied by:

- NOVA microhypervisor conveyed via HIP.
- LAPIC, IOAPIC devices conveyed via ACPI MADT.
- IOMMU devices [17, 18] conveyed via ACPI DMAR or IVRS.
- Firmware runtime services conveyed via UEFI memory map.

#### 8.2.2 I/O Ports

- ACPI fixed registers PM1a\_CNT, PM1b\_CNT, PM2\_CNT conveyed via ACPI FADT.
- SMI\_CMD port conveyed via ACPI FADT.

# 8.3 Physical Memory

#### 8.3.1 Memory Map

The Root Protection Domain (PD<sub>ROOT</sub>) can obtain a list of available/reserved memory regions as follows:

- On platforms using Multiboot v2 (UEFI boot services enabled), by parsing the UEFI memory map [7].
- On platforms using Multiboot v2, by parsing the Multiboot v2 memory map [8].
- On platforms using Multiboot v1, by parsing the Multiboot v1 memory map [9].

# 8.4 Virtual Memory

#### 8.4.1 Host-Virtual Addresses

Depending on the MMU features supported by the hardware platform, the Host-Virtual Address (HVA) range accessible to Host Execution Contexts is  $0 \le \text{HVA} < 2^{\text{H}}$  with  $47 \le \text{H} \le 56$ .

The Root Protection Domain (PD<sub>ROOT</sub>) should determine 2<sup>H</sup> based on the virtual address of the HIP.

#### 8.4.2 Guest-Physical Addresses

Depending on the MMU features supported by the hardware platform, the Guest-Physical Address (GPA) range accessible to Guest Execution Contexts is  $0 \le \text{GPA} < 2^G$  with  $48 \le G \le 57$  and G = H+1.

#### 8.4.3 Cacheability Attributes

Encoding	<b>ATTR</b> <sub>CA</sub>	Description
0x0	WB	Write Back
0x1	WT	Write Through
0x2	WC	Write Combining
0x3	UC	Strong Uncacheable
0x4	WP	Write Protected

Please refer to [4, 5] for details on the architectural behavior.

#### 8.4.4 Shareability Attributes

Encoding ATTR <sub>SH</sub>		Description	
0x0	UNUSED	Always use this value	

#### 8.5 Class Of Service

Class Of Service (COS) support is indicated by CPUID leaf 0x7, sub-leaf 0x0: EBX[15].

The Root Protection Domain (PD<sub>ROOT</sub>) must perform the following steps on each CPU to configure QOS settings:

- 1. Invoke ctrl\_hw to establish a valid QOS configuration:
  - CDPL3 support is indicated by CPUID leaf 0x10, sub-leaf 0x1: ECX[2]
  - CDP<sub>L2</sub> support is indicated by CPUID leaf 0x10, sub-leaf 0x2: ECX<sub>[2]</sub>
- 2. Determine COS<sub>NUM</sub> as the maximum of the following:
  - $COS_{L3}$  from CPUID leaf 0x10, sub-leaf 0x1:  $(1+EDX_{[15-0]})>>X$ , where
    - X=0 if CDP<sub>L3</sub> is disabled.
    - X=1 if  $CDP_{L3}$  is enabled.
  - $COS_{L2}$  from CPUID leaf 0x10, sub-leaf 0x2:  $(1+EDX_{[15-0]})>>X$ , where
    - X=0 if CDP<sub>L2</sub> is disabled.
    - X=1 if  $CDP_{L2}$  is enabled.
  - $COS_{MB}$  from CPUID leaf 0x10, sub-leaf 0x3:  $(1+EDX_{[15-0]})$
- 3. Invoke ctrl\_hw to configure the following:
  - For each COS<sub>L3</sub>: CAT/CDP L3 Capacity Bitmask(s)
  - For each COS<sub>L2</sub>: CAT/CDP L2 Capacity Bitmask(s)
  - For each COS<sub>MB</sub>: MBA Delay

# 8.6 Event-Specific Capability Selectors

For the delivery of exception/intercept messages, the microhypervisor performs an implicit portal traversal.

The selector for the destination portal (SEL<sub>OBJ</sub>):

- is determined by adding the exception/intercept number to the affected Execution Context's Event Selector Base (SEL<sub>EVT</sub>).
- indexes into the Object Space (SPC<sub>OBJ</sub>) of the affected EC's Protection Domain (PD).
- must refer to a PT Capability (CAP<sub>OBJPT</sub>) with permission EVENT that is bound to an EC on the same core as the affected EC, otherwise the affected EC is killed.

#### 8.6.1 Architectural Events

#### **Host Exceptions**

$SEL_{OBJ}$	Exception	$SEL_{OBJ}$	Exception
$SEL_{EVT} + 0x00$	#DE	$SEL_{EVT} + 0x10$	#MF

## 8.7.3 Message Transfer Descriptor

The Message Transfer Descriptor (MTD), which controls the subset of the architectural state transferred during exceptions and intercepts, as described in Section 4.4.2, has the following layout:

Each MTD bit controls the transfer of the listed architectural state to/from the respective fields in the UTCB (8.7.2) as follows:

- State with access r can be read from the architectural state into the UTCB.
- State with access w can be written from the UTCB into the architectural state.

MTD Bit	Access	<b>Host Execution Context State</b>	<b>Guest Execution Context State</b>
POISON	W	Kills the EC <sub>HST</sub>	Kills the EC <sub>GST</sub>
GPR <sub>0-7</sub>	rw	R0 R7	R0 R7
$GPR_{8-15}$	rw	R8 R15	R8 R15
RFLAGS	rw	RFLAGS*	RFLAGS
RIP	rw	RIP	RIP, Instruction Length, Instruction Info
STA	rw	_	Interruptibility State, Activity State
QUAL	r	Qualifications <sup>†</sup>	Qualifications <sup>‡</sup>
CTRL			Execution Controls, CR Intercepts
CIKL	W	_	EXC Intercepts, PF Error Mask/Match
TPR	W	-	TPR Threshold
INJ	rw		Interruption Info, Interruption Error
INJ	r	_	IDT Vectoring Info, IDT Vectoring Error
CS/SS	rw	-	CS, SS (Selector, Base, Limit, AR)
DS/ES	rw	_	DS, ES (Selector, Base, Limit, AR)
FS/GS	rw	_	FS, GS (Selector, Base, Limit, AR)
TR	rw	_	TR (Selector, Base, Limit, AR)
LDTR	rw	_	LDTR (Selector, Base, Limit, AR)
GDTR	rw	_	GDTR (Base, Limit)
IDTR	rw	_	IDTR (Base, Limit)
PDPTE	rw	-	PDPTE0 PDPTE3
CR	rw	_	CR0, CR2, CR3, CR4, CR8
DR	rw	_	DR7
XSAVE	rw	-	XCRO, IA32_XSS
SYSCALL	rw	_	IA32_{STAR,LSTAR,FMASK}
SYSENTER	rw	_	IA32_SYSENTER_{CS,ESP,EIP}
PAT	rw	_	IA32_PAT
EFER	rw	_	IA32_EFER
KERNEL_GS	rw	_	IA32_KERNEL_GS_BASE

TLB	W	-	Invalidates the TLB for the vCPU
SPACES	W	-	SEL_GST, SEL_PIO, SEL_MSR

<sup>\*</sup>Only the status and control flags are writable.

<sup>†</sup>Qualification fields contain exception error code (1st), page-fault linear address (2nd).

<sup>&</sup>lt;sup>‡</sup>Qualification fields contain exit qualification (1st), guest-linear address (2nd), guest-physical address (3rd).

# 8.7.4 Device Assignment Descriptor

The Device Assignment Descriptor (DAD) describes a device to be assigned to a DMA Space ( $SPC_{DMA}$ ). On x86, IOMMU resources need not be specified.

The fields are defined as follows:

#### B, D, F:

Designates the device via its Bus/Device/Function (BDF) source identifier.

# 8.8 Calling Convention

The following pages describes the calling convention for each hypercall. A Host Execution Context calls into the microhypervisor by loading the hypercall identifier and other parameters into the specified CPU registers and then executes the syscall instruction [4, 5].

The hypercall identifier consists of the hypercall number and hypercall-specific flags, as illustrated in Figure 8.1.

Figure 8.1: Hypercall Identifier

The status code returned from a hypercall has the format shown in Figure 8.2.

Figure 8.2: Status Code

The assignment of hypercall parameters to CPU registers is shown on the left side, the contents of the CPU registers after the hypercall is shown on the right side.

# C Console

## **C.1 Memory-Buffer Console**

The NOVA microhypervisor implements a memory-buffer console that provides run-time debug output. The memory-buffer console consists of a signaling semaphore (see 6.1.2) and an in-memory data structure with a header and a buffer as follows:

The start address and end address of the memory-buffer console are conveyed in the HIP.

The buffer size (N characters) can be computed as:

The fields of the header are used as follows:

- RdIdx ranges from 0 ... N-1.
   It points to the next character in the buffer that the console consumer will read and is typically advanced by the console consumer.
- WrIdx ranges from 0 ... N-1.
   It points to the next character in the buffer that the NOVA microhypervisor will write and is only advanced by the NOVA microhypervisor.
- The buffer is empty if RdIdx is equal to WrIdx.
- Otherwise WrIdx is ahead of RdIdx, wrapping around the buffer size N accordingly, i.e. character N+x will be stored in the same buffer slot as character x.
- If the buffer becomes full, the NOVA microhypervisor advances RdIdx, forcing the oldest character to be discarded from the buffer.
- At the end of each line, the NOVA microhypervisor invokes ctrl\_sm (Up) on the signaling semaphore. The console consumer should use ctrl\_sm (Down) on the signaling semaphore instead of polling Wrldx.

#### C.2 UART Console

Additionally several different UART consoles can be used to provide boot-time-only debug output of the microhypervisor. UART consoles must be configured for 115200 baud and 8N1 mode.
